

Standard Test Methods for Minimum Index Density and Unit Weight of Soils and Calculation of Relative Density¹

This standard is issued under the fixed designation D4254; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

This standard has been approved for use by agencies of the Department of Defense.

^{ε1} NOTE—Corrected research report reference in Section 12 editorially in March 2008.

1. Scope*

1.1 These test methods cover the determination of the minimum-index dry density/unit weight of cohesionless, free-draining soils. The adjective “dry” before density or unit weight is omitted in the title and remaining portions of this standards to be consistent with the applicable definitions given in Section 3 on Terminology.

1.2 System of units:

1.2.1 The testing apparatus described in this standard has been developed and manufactured using values in the gravimetric or inch-pound system. Therefore, test apparatus dimensions and mass given in inch-pound units are regarded as the standard.

1.2.2 It is common practice in the engineering profession to concurrently use pounds to represent both a unit of mass (lbm) and a unit of force (lbf). This implicitly combines two separate systems of units; that is, the absolute system and the gravitational system. It is scientifically undesirable to combine the use of two separate sets of inch-pound units within a single standard. This test method has been written using the gravitational system of units when dealing with the inch-pound system. In this system, the pound (lbf) represents a unit of force (weight). However, balances or scales measure mass; and weight must be calculated. In the inch-pound system, it is common to assume that 1 lbf is equal to 1 lbm. While reporting density is not regarded as nonconformance with this standard, unit weights should be calculated and reported since the results may be used to determine force or stress.

1.2.3 The terms density and unit weight are often used interchangeably. Density is mass per unit volume, whereas unit weight is force per unit volume. In this standard, density is given only in SI units. After the density has been determined, the unit weight is calculated in SI or inch-pound units, or both.

¹ This test method is under the jurisdiction of ASTM Committee D18 on Soil and Rock and is the direct responsibility of Subcommittee D18.03 on Texture, Plasticity and Density Characteristics of Soils.

Current edition approved Feb. 1, 2006. Published March 2006. Originally approved in 1983. Last previous edition approved in 2000 as D4254 – 00. DOI: 10.1520/D4254-00R06E01.

1.3 Three alternative methods are provided to determine the minimum index density/unit weight, as follows:

1.3.1 Method A—Using a funnel pouring device or a hand scoop to place material in mold.

1.3.2 Method B—Depositing material into a mold by extracting a soil filled tube.

1.3.3 Method C²—Depositing material by inverting a graduated cylinder.

1.4 The method to be used should be specified by the individual assigning the test. If no method is specified, the provisions of Method A shall govern. Test Method A is the preferred procedure for determining minimum index density/unit weight as used in conjunction with the procedures of Test Methods D4253. Methods B and C are provided for guidance of testing used in conjunction with special studies, especially where there is not enough material available to use a 0.100 ft³ (2830 cm³) or 0.500 ft³ (14 200 cm³) mold as required by Method A.

1.5 These test methods are applicable to soils that may contain up to 15 %, by dry mass, of soil particles passing a No. 200 (75- μ m) sieve, provided they still have cohesionless, free-draining characteristics (nominal sieve dimensions are in accordance with Specification E11).

1.5.1 Method A is applicable to soils in which 100 %, by dry mass, of soil particles pass a 3-in. (75-mm) sieve and which may contain up to 30 %, by dry mass, of soil particles retained on a 1½-inch (37.5-mm) sieve.

1.5.2 Method B is applicable to soils in which 100 %, by dry mass, of soil particles pass a ¾-inch (19.0-mm) sieve.

1.5.3 Method C is applicable only to fine and medium sands in which 100 %, by dry mass, of soil particles pass a ¾-in. (9.5-mm) sieve and which may contain up to 10 %, by dry mass, of soil particles retained on a No. 10 (2.00-mm) sieve.

1.5.4 Soils, for the purposes of these test methods, shall be regarded as naturally occurring cohesionless soils, processed

*A Summary of Changes section appears at the end of this standard

particles, or composites or mixtures of natural soils, or mixtures of natural and processed particles, provided they are free-draining.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. Terminology

3.1 *Definitions*—For common definitions in this standard refer to Terminology [D653](#).

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *dry density/unit weight* ρ_d or γ_d n —the dry density/unit weight of a soil deposit or fill at the given void ratio.

3.2.2 *given void ratio*, e , n —the in-situ or stated void ratio of a soil deposit or fill.

3.2.3 *maximum index density/unit weight*, ρ_{dmax} or γ_{dmax} n —the reference dry density/unit weight of a soil in the densest

state of compactness that can be attained using a standard laboratory compaction procedure that minimizes particle segregation and breakdown.

3.2.4 *maximum-index void ratio*, e_{max} n —the reference void ratio of a soil at the minimum index density/unit weight.

3.2.5 *minimum index density/unit weight* ρ_{demon} or γ_{demon} n —reference dry density/unit weight of a soil in the loosest state of compactness at which it can be placed using a standard laboratory procedure that prevents bulking and minimizes particle segregation.

3.2.6 *minimum-index void ratio*, e_{min} n —the reference void ratio of a soil at the maximum index density/unit weight.

3.2.7 *relative density*, D_d n —the ratio, expressed as a percentage, of the difference between the maximum index void ratio and any given void ratio of a cohesionless, free-draining soil to the difference between its maximum and minimum index void ratios. The equation is:

$$D_d = \frac{e_{max} - e}{e_{max} - e_{min}} \times 100 \quad (1)$$

or, in terms of corresponding dry densities:

$$D_d = \frac{\rho_{dmax}(\rho_d - \rho_{demon})}{\rho_d(\rho_{dmax} - \rho_{demon})} \times 100 \quad (2)$$

or, in terms of corresponding dry unit weights:

$$D_d = \frac{\gamma_{dmax}(\gamma_d - \gamma_{demon})}{\gamma_d(\gamma_{dmax} - \gamma_{demon})} \quad (3)$$

3.2.8 *density index/unit weight*, I_d n —the ratio, expressed as a percentage, of the difference between any given dry density/unit weight and the minimum index density/unit weight of a given cohesionless soil to the difference between its maximum and minimum index densities/unit weights. The equation is:

$$I_d = \frac{\rho_d - \rho_{demon}}{\rho_{dmax} - \rho_{demon}} \times 100 \quad (4)$$

or, in terms of corresponding dry unit weights:

$$I_d = \frac{\gamma_d - \gamma_{demon}}{\gamma_{dmax} - \gamma_{demon}} \times 100 \quad (5)$$

4. Summary of Test Method

4.1 The minimum index density/unit weight represents the loosest condition of a cohesionless, free-draining soil that can be attained by a standard laboratory procedure, which prevents bulking and minimizes particle segregation. Any particular procedure selected will consist of determining the density/unit weight of oven-dried soil placed into a container of known volume in such a manner that prevents bulking and particle segregation, and minimizes compaction of the soil.

5. Significance and Use

5.1 The density/unit weight of a cohesionless soil may be determined by various in-place methods in the field or by the measurement of physical dimensions and masses by laboratory soil specimens. The dry density/unit weight of a cohesionless soil does not necessarily, by itself, reveal whether the soil is loose or dense.

³ For referenced ASTM standards, visit the ASTM website, www.astm.org, or contact ASTM Customer Service at service@astm.org. For *Annual Book of ASTM Standards* volume information, refer to the standard's Document Summary page on the ASTM website.

5.2 Relative density/unit weight expresses the degree of compactness of a cohesionless soil with respect to the loosest and densest condition as defined by standard laboratory procedures. Only when viewed against the possible range of variation, in terms of relative density/unit weight, can the dry density/unit weight be related to the compaction effort used to place the soil in a compacted fill or indicate volume change and stress-strain tendencies of soil when subjected to external loading.

5.3 An absolute minimum density/unit weight is not necessarily obtained by these test methods.

NOTE 1—In addition, there are published data to indicate that these test methods have a high degree of variability.⁴ However, the variability can be greatly reduced by careful calibration of equipment, and careful attention to proper test procedure and technique.

5.4 The use of the standard molds (6.3.1) has been found to be satisfactory for most soils requiring minimum index density/unit weight testing. Special molds (6.3.2) shall only be used when the test results are to be applied in conjunction with design or special studies and there is not enough soil to use the standard molds. Such test results should be applied with caution, as minimum index densities/unit weights obtained with the special molds may not agree with those that would be obtained using the standard molds.

NOTE 2—The quality of the result produced by this standard is dependent on the competence of the personnel performing it, and the suitability of the equipment and facilities used. Agencies that meet the criteria of Practice D3740, generally, are considered capable of competent and objective testing/sampling/inspection/etc. Users of this standard are cautioned that compliance with Practice D3740 does not in itself assure reliable results. Reliable results depend on many factors; Practice D3740 provides a means of evaluating some of those factors.

6. Apparatus

6.1 Apparatus for Methods A, B, and C:

6.1.1 *Drying Oven*, thermostatically controlled, preferably of the forced-draft type, capable of maintaining a uniform temperature of $230 \pm 9^\circ\text{F}$ ($110 \pm 5^\circ\text{C}$) throughout the drying chamber.

6.1.2 *Sieves*, 3-in. (75-mm), 1½-in. (37.5-mm), ¾-in. (19-mm), ⅜-in. (9.5-mm), No. 4 (4.75-mm), No. 10 (2.00-mm), and No. 200 (75- μm) conforming to the requirements of Specification E11.

6.2 The apparatus for determining the minimum index density/unit weight of cohesionless soil by Methods A and B is specified in 6.3. Apparatus required for Method C is specified in 6.4.

6.3 Apparatus for Methods A and B:

6.3.1 *Standard Molds*—Cylindrical metal molds having nominal volumes of 0.1000 ft³ (2830 cm³) and 0.500 ft³ (14 200 cm³). The molds shall conform to the requirements shown in Fig. 1. The actual volume of the molds shall be within $\pm 1.5\%$ of the specified nominal volume.

6.3.2 *Special Molds*—Cylindrical metal molds having a capacity less than 0.100 ft³ (2830 cm³), an inside diameter

equal to or greater than 2¾ in. (70 mm) but less than 4 in. (100 mm) and conforming to the design methodology presented in Fig. 2. Such molds may only be used when the test results are to be used in conjunction with design or special studies, and there is not enough soil to use the 0.100 ft³ (2830 cm³) mold.

6.3.3 *Balances(s)*, of sufficient capacity to determine the total mass of the specimen and mold, having sufficient accuracy that the mass of the soil is determined to the nearest 0.1 %. Balances capable of satisfying these requirements for most conditions have specifications as follows:

6.3.3.1 For 0.500-ft³ (14 200-cm³) molds, use a balance having a minimum capacity of 40-kg and meeting the requirements of Specification D4753 for a Class GP 10 (readability of 5 g).

6.3.3.2 For 0.100-ft³ (2830-cm³) molds, use a balance having a minimum capacity of at least 15 kg and meeting the requirements of Specification D4753 for Class GP 5 (readability of 1 g).

6.3.3.3 For special molds that are less than 0.1 ft³ (2830 cm³) in capacity, use a balance having a minimum capacity of at least 2 kg and meeting the requirements of Specification D4753 for a Class GP 2 (readability of 0.1 g).

6.3.4 *Pouring Devices*, are used in conjunction with the 0.100 ft³ (2830 cm³) standard mold and with special molds. Pouring devices consist of relatively rigid containers having volumes about 1.25 to 2 times greater than the volumes of the mold(s) used, and fitted with spouts or tubes about 6 in. (150 mm) long. Two pouring spouts are required, one having an inside spout diameter of 0.50 in. (13 mm) and another with an inside spout diameter of 1.0 in. (25 mm). A lipped brim, or other means, must be provided to securely connect the spout to the container that permits free and even flow of the soil from the container into the spout, and then into the mold.

6.3.5 *Rigid, Thin-Walled Tubes*, for use with Method B. The size of the tubes is dependent upon the mold size selected. The volume of the tubes shall be between 1.25 and 1.30 times the volume of the mold. The inside diameter of the tube shall be about 0.7 times the inside diameter of the mold.

6.3.6 Other equipment such as mixing pans, a large metal scoop, a hair-bristled dusting brush, and a metal straightedge (for trimming excess soil after it has been placed in the mold).

6.4 Apparatus for Method C:

6.4.1 *Glass Graduated Cylinder*, having a volume of 2000 mL, graduated to 20 mL, with about a 3-in. (75-mm) inside diameter.

6.4.2 *Balance*, of at least 2 kg capacity and otherwise consistent with 6.3.3.3.

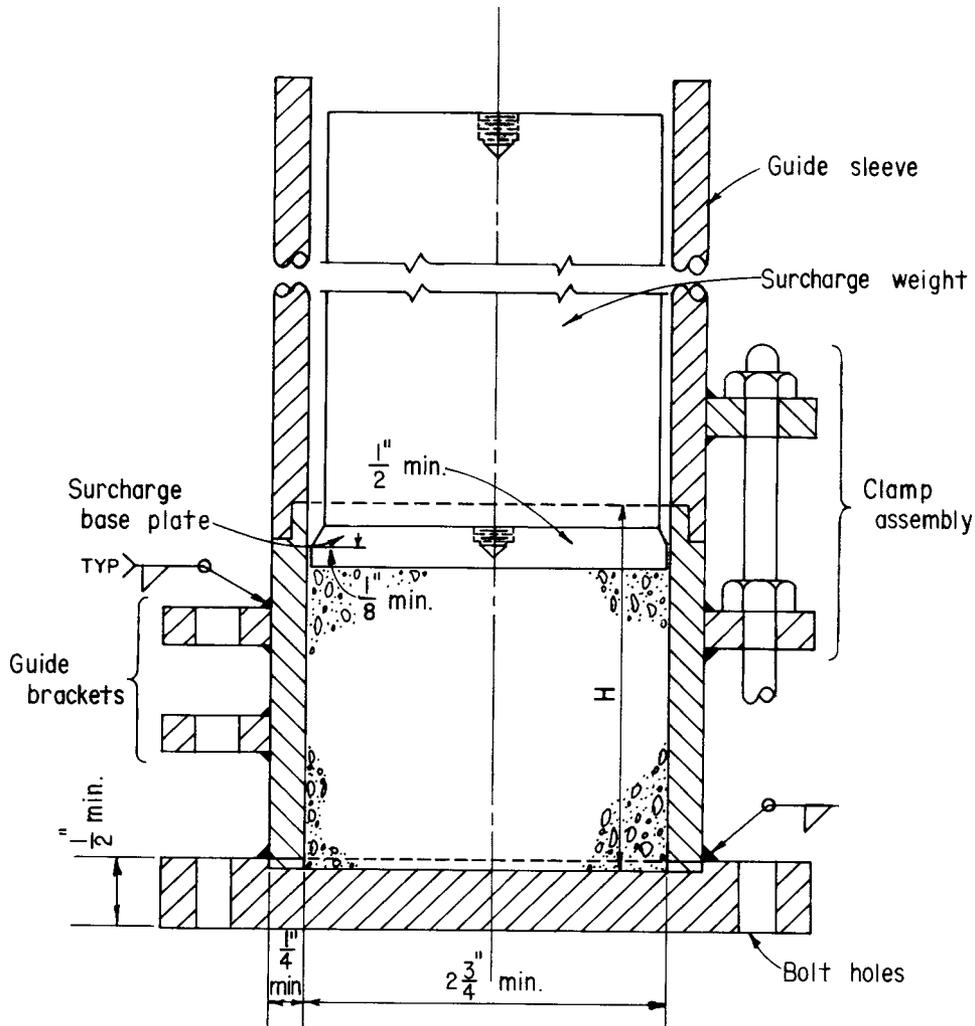

6.4.3 *Sieves*, ⅜-in. (9.5-mm), No. 10 (2.00-mm), and No. 200 (75- μm) sieves conforming to the requirements of Specification E11.

7. Sampling and Test Specimen

7.1 Prior to testing, the sample should be stored in a manner to prevent freezing, contamination with other matter, loss of soil, or loss of identification.

7.2 Sampling and test specimen requirements for Methods A and B are contained in the following paragraphs. Requirements for Method C begin at 7.4.

⁴ Selig, E. T., and Ladd, R. S., eds., Evaluation of Relative Density and its Role in Geotechnical Projects Involving Cohesionless Soils, ASTM STP 523, ASTM, 1973.

FIG. 2 Special Cylindrical Metal Molds

TABLE 1 Required Mass of Specimen

Maximum Size 100% Passing, in. (mm)	Mass of Specimen Required, kg	Placement Device to be Used in Minimum Density Test	Size of Mold to Be Used, ft ³ (cm ³)
3 (75)	34	shovel or extra large scoop	0.500 (14 200)
1 1/2 (38.1)	34	scoop	0.500 (14 200)
3/4 (19.0)	11	scoop	0.100 (2830)
3/8 (9.5)	11	pouring device with 1-in. (25-mm) diameter spout	0.100 (2830)
No. 4 (4.75) or less	11	pouring device with 1/2-in. (13-mm) diameter spout	0.100 (2830)

M_r = mass required, kg, and
 V_m = volume of mold, cm³.

7.4 Select a representative specimen of soil that meets the requirements of 7.3, using a splitter, riffle, or other method

such as quartering. For Method C, the specimen should have a mass of about 1.5 kg.

7.5 Dry the specimen in the drying oven, maintained at 110 ± 5°C to a constant mass. Oven-dried sand, for use with

Method C, shall be permitted to cool in an airtight container. It is often desirable to obtain the water content of the field sample. If this is the case, determine the water content in accordance with Test Method **D2216**.

7.5.1 After drying, thoroughly break up the weakly cemented aggregations as to avoid reducing the natural size of the particles.

8. Calibration

8.1 *Molds*—The volume and cross-sectional area of each mold should be calibrated before initial use and at intervals not exceeding each 1000 times the mold is used for testing, or annually, whichever occurs first. Determine the volume of each mold by either the direct-measurement method or the water-filling method as provided in **8.1.1** and **8.1.2**. The volume obtained by either method should be within $\pm 1.5\%$ of the nominal value. It is recommended that both the direct-measurement and water-filling methods be used. If the difference between the volumes calculated from the two methods exceeds 0.5% of the nominal value of the mold being calibrated, then the calibration should be repeated. Failure to obtain agreement between the two calibration methods within the stated tolerances, even after several trials, is an indication that the mold is badly deformed and should be replaced. If both calibration methods are performed, the volume obtained by the water-filling method should be assigned to the mold (this method more accurately reflects the conditions over the entire mold).

8.1.1 *Direct Measurement Method*—The volume of the mold is calculated from the average of at least three internal-diameter and three height measurements, evenly spaced throughout the mold, made to the nearest 0.001 in. (0.025 mm). Calculate and record the height in inches, millimeters, or centimeters to four significant digits (in accordance with Practice **D6026**). Calculate and record the volume, V_m (cm^3) to four significant digits (in accordance with Practice **D6026**).

8.1.2 *Water-Filling Method*—Completely fill the mold with water. Slide a glass plate carefully over the top surface (rim) of the mold as to ensure that the mold is completely filled with water. A thin film of grease or silicone lubricant on the rim of the mold will make a watertight joint between the glass plate and rim of the mold. Determine the mass of water required to fill the mold, using the appropriate balance specified in **6.3.3**. Determine the temperature of this water to the nearest 1°C . From **Table 2** obtain the unit volume of water in millilitres per gram (mL/g) at the observed temperature. Calculate and record the volume of the mold (m^3 or cm^3) to four significant digits, as follows:

8.1.2.1 For mass measurements in grams, calculate the volume in cubic centimetres (cm^3) by multiplying the mass of water (g) used to fill the mold by the volume of water per gram (mL/g), from **Table 2** and noting $\text{mL} = \text{cm}^3$. To determine the volume in cubic metres (m^3), multiply volume in cm^3 by 1×10^{-6} .

8.2 Determine and record the mass of the empty mold, using the appropriate balance specified in **6.3.3**.

TABLE 2 Volume of Water per Gram Based on Temperature^A

9. Procedure

9.1 The steps for performing Method A, the preferred procedure, shall be in accordance with **9.2**. The Method B procedure is given in **9.3** and Method C in **9.4**.

9.2 Method A:

9.2.1 Mix the oven-dried specimen to provide an even distribution of particle sizes.

9.2.2 If the pouring device (as required in **Table 1**) is used, place the soil as loosely as possible in the mold by pouring the soil from the spout (**Table 1**) in a steady stream, holding the pouring device upright and vertical or nearly vertical. Continuously adjust the height of the spout to maintain a free fall of the soil of about $\frac{1}{2}$ in. (13 mm) or just high enough to maintain continuous flow of soil particles without the spout contacting the already deposited soil. Move the pouring device in a spiral path from the outside to the center of the mold to form each layer of nearly uniform thickness. Spiraling motion should be just sufficient to minimize particle segregation.

NOTE 3—Static electricity in dry sand can cause bulking similar to that produced by a trace of moisture on the particles; a static-eliminating balance brush can be applied to the equipment in contact with the sand when this effect becomes bothersome.

9.2.2.1 Fill the mold approximately $\frac{1}{2}$ in. (13 mm) to 1 in. (25 mm) above the top of the mold (or until all points of the soil surface are above the plane of the mold rim).

9.2.2.2 Trim off the excess soil level with the top by carefully trimming the soil surface with a straightedge. Great care must be exercised during filling and trimming operations to avoid jarring the mold or excessively disturbing the soil surface and causing rearrangement and settlement of the soil particles. Making one continuous pass with the straightedge, or if necessary, two passes, has produced the most reproducible results.

9.2.3 If the scoop or shovel (as required in **Table 1**) are used, place the soil as loosely as possible by holding the scoop or shovel just above the soil surface to cause the material to slide rather than fall onto the previously placed soil. If necessary, holding large particles back by hand to prevent them from rolling off the scoop/shovel.

9.2.3.1 Fill the mold to overflowing but not more than 1 in. (25 mm) above the top. For soils where the maximum particle size passes the 3/4-in. (19.0-mm) sieve, use the steel straight-edge (and the fingers when needed) to level the surface of the soil with the top of the mold. For soils with a large maximum particle size, use the fingers in such a way that any slight projections of the larger particles above the top of the mold shall approximately balance the larger voids in the surface below the top of the mold.

9.2.4 Determine and record the mass of the mold plus soil, using the appropriate balance specified in 6.3.3. Calculate and record the mass of the soil filling the mold by subtracting the mass of the empty mold, as determined in 8.2, from the mass of the mold and soil. Calculate the minimum index density/unit weight, $\rho_{dmin,n}$ or $\gamma_{dmin,n}$, in accordance with Section 10.

9.2.5 Steps 9.2.1-9.2.4 should be repeated until consistent values of minimum index density/unit weight (preferably within 1 %) are obtained.

9.3 Method B:

9.3.1 Mix the oven-dried specimen to provide an even distribution of particle sizes.

9.3.2 Select the proper sized thin-walled tube in accordance with the requirements of 6.3.5.

9.3.3 Place the tube inside the mold. Place cohesionless soil into the tube with a pouring device, scoop, or spoon, being careful to minimize segregation of material during filling. Fill the tube within 1/8 in. (3 mm) to 1/4 in. (6 mm) of the top.

9.3.4 Quickly raise the tube allowing the cohesionless material to overfill the mold, see 9.2.2.1.

9.3.5 Following procedures given in 9.2.2.2 or 9.2.3.1, trim the soil surface level with the top of the mold.

9.3.6 Determine and record the mass of the mold plus soil, using the appropriate balance specified in 6.3.3. Calculate and record the mass of the soil filling the mold by subtracting the mass of the empty mold, as determined in 8.2, from the mass of the mold plus soil. Calculate the minimum index density/unit weight, $\rho_{dmin,n}$ or $\gamma_{dmin,n}$, in accordance with Section 10.

9.3.7 Steps 9.3.1-9.3.6 should be repeated until consistent values of minimum index density/unit weight (preferably within 1 %) are obtained.

9.4 Method C²:

9.4.1 Place 1000 ± 1 g of sand in a 2000-mL graduated cylinder and place a stopper in the top of the cylinder. Tip the cylinder upside down, and then quickly tilt it back to the original vertical position.

9.4.2 Record the volume that the sand occupies in the graduated cylinder, V_g . Calculate the minimum index density/unit weight in accordance with Section 10.

9.4.3 Repeat the procedure until three consistent values of the minimum index density/unit weight (preferably within 1 %) are obtained.

10. Calculation

10.1 Calculate the minimum (dry) index density for each trial as follows:

$$\rho_{dmin,n} = \frac{M_s}{V} \quad (7)$$

where:

$\rho_{dmin,n}$ = minimum index density for given trial, Mg/m³ or g/cm³

M_s = mass of the tested-dry soil, Mg or g, and

V = volume of the tested-dry soil, m³ or cm³. For Methods A and B, $V=V_c$ or calibrated volume of mold; and for Method C, $V=V_g$ (see 9.4.2)

10.1.1 Calculate the average of the minimum-index density values, $\rho_{dmin,n}$, from the trials that agree within 1 %. This average value is to be recorded/reported as the minimum index density, ρ_{demon} , of the test specimen.

10.1.2 If requested, calculate the minimum-index unit weight of the specimen as follows:

$$\gamma_{demon} = 9.807 \cdot \rho_{demon}, \text{ kN/m}^3 \quad (8)$$

or

$$\gamma_{demon} = 62.428 \times \rho_{demon}, \text{ lbf/ft}^3$$

10.2 If requested, calculate the maximum-index void ratio, e_{max} , as follows:

$$e_{max} = \frac{\rho_w \cdot G_{avg}}{\rho_{demon}} - 1 \quad (9)$$

where:

e_{max} = maximum-index void ratio,

ρ_w = density of water at 20°C (0.99821) or equal to 1.0 Mg/m³ or g/cm³

G_{avg} at 20 °C = weighted average specific gravity of soils composed of particles larger and smaller than the No. 4 (4.75-mm) sieve, or

$$G_{avg} \text{ at } 20^\circ\text{C} = \frac{1}{\frac{R}{100 \cdot G_{1 \text{ at } 20^\circ\text{C}}} + \frac{P}{100 \cdot G_{2 \text{ at } 20^\circ\text{C}}}} \quad (10)$$

where:

$G_{1 \text{ at } 20^\circ\text{C}}$ = apparent specific gravity of the soil particles retained on the No. 4 (4.75-mm) sieve as determined by Test Method C127 and corrected to 20°C (see Test Methods D854),

$G_{2 \text{ at } 20^\circ\text{C}}$ = specific gravity of the soil particles passing the No. 4 (4.75-mm) sieve as determined by Test Methods D854,

R = percentage of soil particles from the sample retained on the No. 4 (4.75-mm) sieve, and

P = percentage of soil particles from the sample passing the No. 4 (4.75-mm) sieve.

10.3 If the maximum index density/unit weight, ρ_{dmax} or γ_{dmax} , has been determined in accordance with Test Methods D4253 and the soil deposit or fill dry density/unit weight, ρ_d or γ_d , or void ratio, e , is known, the relative density, D_r , can be calculated as calculated by any of the equations given in 3.2.7, i.e., Equations 1, 2, or 3.

11. Report

11.1 Report the following information:

11.1.1 Origin of material used in the test.

11.1.2 Description of appearance of test specimen, based on Practice D2488 (Practice D2487 may be used as an alternative).

11.1.3 The method (Methods A, B, or C) and size of mold used.

11.1.4 The minimum index density/unit weight, ρ_{demon} , in Mg/m^3 or g/cm^3 or minimum index unit weight, γ_{demon} , in lb/ft^3 (kN/m^3) to three or four significant digits (in accordance with Practice D6026).

12. Precision and Bias⁵

12.1 *Precision*—Criteria for judging the acceptability of test results obtained by these test methods, using Method A and testing a poorly graded sand (SP), is given in Tables 3 and 4. These estimates of precision are based on the results of the interlaboratory program conducted by the ASTM Reference soils and Testing Program. In this program, some laboratories performed three replicate tests per soil type (triplicate-test laboratory), while other laboratories performed a single test per soil type (single-test laboratory). A description of the soil tested is given in 12.1.4. The precision estimates may vary with soil type and method used (Method A, B, or C). Judgment is required when applying these estimates to another soil or method.

⁵ Supporting data have been filed at ASTM International Headquarters and may be obtained by requesting Research Report RR:D18-1011.

TABLE 3 Summary of Test Results from Triplicate Test Laboratories (Minimum Index Unit Weight)

(1)	(2)	(3)	(4)	(5)
Soil Type	Number of Triplicate Test Laboratories	Average Value ^A (lb/ft ³)	Standard Deviation ^B (lb/ft ³)	Acceptable Range of Two Results ^C (lb/ft ³)
<i>Single-Operator Results (Within-Laboratory Repeatability):</i>				
SP	8	98.17	0.50	1.4
<i>Multilaboratory Results (Between-Laboratory Reproducibility):</i>				
SP	8	98.17	2.49	6.9

^A The number of significant digits and decimal places presented are representative of the input data. In accordance with Practice D6026, the standard deviation and acceptable range of results can not have more decimal places than the input data.

^B Standard deviation is calculated in accordance with Practice E691 and is referred to as the 1s limit.

^C Acceptable range of two results is referred to as the d2s limit. It is calculated as $1.960\sqrt{2} \cdot 1s$, as defined by Practice E177. The difference between two properly conducted tests should not exceed this limit. The number of significant digits/decimal places presented is equal to that prescribed by these test methods or Practice D6026. In addition, the value presented can have the same number of decimal places as the standard deviation, even if that result has more significant digits than the standard deviation.

TABLE 4 Summary of Single-Test Result from Each Laboratory (Minimum Index Unit Weight)^A

(1)	(2)	(3)	(4)	(5)
Soil Type	Number of Test Laboratories	Average Value ^A (lb/ft ³)	Standard Deviation ^B (lb/ft ³)	Acceptable Range of Two Results ^C (lb/ft ³)
<i>Multilaboratory Results—Reproducibility (Single-Test Performed by Each Laboratory)</i>				
SP	12	97.54	2.63	7.3

^A See Footnotes in Table 3.

12.1.1 The data in Table 3 are based on three replicated tests performed by each triplicate test laboratory on the SP sand. The single operator and multilaboratory standard deviation shown in Table 3, Column 4 were obtained in accordance with Practice E691, which recommends each testing laboratory perform a minimum of three replicate tests. Results of two properly conducted tests performed by the same operator on the same material, using the same equipment, and in the shortest practical period of time should not differ by more than the single-operator d2s limits shown in Table 3, Column 5. For definition of d2s, see Footnote C in Table 3. Results of two properly conducted tests performed by different operators and on different days should not differ by more than the multilaboratory d2s limits show in Table 3, Column 5.

12.1.2 In the ASTM Reference Soils and Testing Program, many of the laboratories performed only a single test. This is common practice in the design and construction industry. The data in Table 4 are based upon the first test results from the triplicate test laboratories and the single test results from the other laboratories. Results of two properly conducted tests performed by two different laboratories with different operators using different equipment and on different days should not vary by more than the d2s limits shown in Table 4, Column 5. The results in Table 3 and Table 4 are dissimilar because the data sets are different.

12.1.3 Table 3 presents a rigorous interpretation of triplicate test data in accordance with Practice E691 from pre-qualified laboratories. Table 4 is derived from test data that represents common practice.

12.1.4 Soil Type:

SP—Poorly graded sand, SP 20 % coarse sand, 48 % medium sand, 30 % fine sand, 2 % fines, yellowish brown. Local name—Frederick sand.

12.2 *Bias*—There is no accepted reference value for these test methods, therefore, bias cannot be determined.

13. Keywords

13.1 minimum index density; minimum index unit weight; relative density

SUMMARY OF CHANGES

In accordance with D-18 policy, this section identifies the location of changes to this standard since the last edition (91(Reapproved 1996)) that may impact the use of this standard:

- (1) A Summary of Changes Section was added.
- (2) “Test Method(s)” was changed to “Method(s)” where applicable.
- (3) Reworded 1.1-1.2.3 and in 1.1 added sentence covering the usage of “dry”.
- (4) Under Terminology, changed the order in which some terms are presented and corrected equations so the resultant is in percent.
- (5) References to Practices D3740, D6026, E177, and E691 were included throughout the text where applicable. References to Practice E380 were deleted as Practice D6026 replaces it.
- (6) Added Note 2 to Section 5 and all subsequent notes were renumbered.
- (7) In 6.3.3.1-6.3.3.3 under balances gave the required readability for the specified balance.
- (8) Under Sampling and Test Specimen in 7, changed the order in which the first two subsections are presented.
- (9) Under Calibrations in 8.1.2, reworded how the mass of water is to be determined (use the appropriate balance specified in the Apparatus section). In 8.1.2, reworded so the calculated volume is in cm³ or m³, not ft³. Removed 8.1.2.2.
- (10) The mL/g constants in Table 2 were updated to agree with the density of water given in Test Methods D854. Also, values at one °C intervals were included and the reference was changed to agree with Test Methods D854.
- (11) Under Procedures in 9.2.4 and 9.3.6, reworded to define which balance is to be used.
- (12) In 10.1, changed notation in the equation to indicate the density is for given trial.
- (13) In 10.1.1, reworded to define the average density for acceptable trials is the minimum index density of the test specimen.
- (14) In 10.1.2 and 10.2, reworded to indicate the calculation is not required. In addition, the equation in 10.1.2 for minimum-index unit weight was corrected, and equation in 10.2 for void ratio was modified so the applicable values are at 20°C.
- (15) Section 11.1.4 was revised to be compliant with Practice D6026.
- (16) In Table 1, the title for maximum particle size was modified to agree with that give in Test Methods D1140.
- (17) Section 12 was thoroughly revised.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.
